PREFACE

A SURVEY of changing aspects of the urban relief population was made in 1935, in a sample of 13 cities, by the Division of Research, Statistics, and Finance, of the Federal Emergency Relief Administration. Several bulletins have been published as a result of the survey. However, the statistical data as a whole have not been made available. This report presents these data for the entire year along with a brief topical analysis indicating the principal findings of the study. The report was prepared in the Division of Research, Works Progress Administration, by F. L. Carmichael and R. Nassimbene, under the supervision of John N. Webb, Coordinator of Urban Research. Special acknowledgment is made of the contribution of John W. Mitchell who collaborated in the preparation of the tabular material, Charles H. Wagner who supervised the editing of the schedules and the tabulation of the data, and Mary Parker Ragatz who edited the report.

Changing Aspects of Urban Relief

INTRODUCTION

AS THE Works Program becomes more generally recognized as an efficient method of assisting the unemployed, there is danger that some of the salient features of Federal participation in direct relief under the Federal Emergency Relief Administration may be obscured. Proposals for a return to direct relief recur so persistently that the experiences of the years 1933 to 1935 have much more than a historical interest.

This report does not attempt an evaluation of direct relief. Nor does it cover the entire period during which direct relief was the principal form of assistance. Instead, it attempts the much less ambitious task of describing the operation of direct relief in a representative sample of 13 cities during the year 1935 when the transfer from direct relief to the Works Program was made. The data presented are drawn from studies made during 1935 for the purpose of describing the changing aspects of urban relief. For specific months and on specific topics the results of these studies have already been published,¹ but the results

for the entire year and for the full range of topics are brought together in this bulletin for the first time.

The more important facts about relief cases, persons, and workers are presented in simple topical form. Appendix tables support the text discussion. The report does not attempt an exhaustive analysis of these facts. When time has brought perspective and a fuller understanding of the problem of unemployment and relief, it will be possible to write a fully integrated story of the period of direct relief. When that time comes the present report should be of considerable assistance.

For ready reference the sections of this report are arranged under broad headings pertaining to the following subjects: proportion of the population receiving relief or wage assistance; trends of the relief and wage assistance load; accession and separation rates; reasons for opening and closing relief cases; occupational and industrial shifts of experienced workers; supplementation of private-employment earnings with relief; unemployment duration and reemployment; and transfers to the Works Program.

Sufficient detail is presented under each heading to show variations according to the personal and economic characteristics of the recipients of assistance. Liberal use has been made of subheadings both to permit easy reference and to simplify the task of putting together such a large mass of material in readable form. Tables supporting the text statements are to be found in the statistical appendix.

The 13 cities selected for the survey were: Atlanta, Ga.; Baltimore, Md.; Bridgeport, Conn.; Butte, Mont.; Chicago, Ill.; Detroit, Mich.; Houston, Tex.; Manchester, N. H.; Omaha, Nebr.; Paterson, N. J.; St. Louis, Mo.; San Francisco, Calif.; and Wilkes-Barre, Pa. These cities are drawn from widely separated sections of the country; both large and small cities are included among them, and every major industry of the country is represented in at least 1 of the 13. Some industries—notably automobile manufacturing—are overrepresented; mineral extraction and textile manufacturing are underrepresented. Because of the importance of the Negro population in most of the large cities included in the survey, there is overrepresentation of Negroes. However, statistical tests show that the relief population of these cities is generally representative of the total urban relief population in respect to age, sex, and occupational background.

Division of Social Research, Works Progress Administration, Washington, D. C., January 15, 1936.

CHANGING ASPECTS OF URBAN RELIEF

PROPORTION OF THE GENERAL POPULATION IN 13 CITIES RECEIVING RELIEF OR WAGE ASSISTANCE DURING 1935

THE RELIEF population may be described in terms of three different units. If the interest is in the general characteristics of all persons in the relief population, the relief *person* is the proper unit of study; if the primary interest is in the family as the relief unit, then attention is focused upon the relief *case*; and if the interest is in those persons who are either working or seeking work, the relief *worker* is the unit for study. In the present chapter analysis and discussion are presented in terms of each of these three units.¹

The general population of the 13 cities in 1935 was estimated at 9,104,000 persons.² Of this number 1,276,600 or 14 percent were on the relief rolls in December 1934. During the year 218,000 persons, constituting 2 percent of the inhabitants of these cities, received relief for the first time³ (appendix table 1). An estimated additional 2 percent had received relief prior to 1935 and were readmitted to the relief registers during the year. If these 2 groups be added to the 14 percent on relief in the 13 cities in December 1934, it may be seen that about 18 percent of the population received relief at some time within the 13-month period December 1934 through December 1935.

For urban United States as a whole there were an estimated 11,400,000 persons receiving relief in December 1934 or about

¹A relief *case* consists of one or more related or unrelated persons living together, receiving aid as one unit, and considered as one case by the agency giving this aid. *Persons* include all members of cases. *Workers* comprise all members 16—64 years of age, inclusive, either working or seeking work.

²General population estimate for the 13 cities as of July 1, 1935. The method of making the 13-city estimates is that set forth in the release of the Bureau of the Census, *Estimated Population of the United States as of July 1, 1935*, U. S. Department of Commerce, Washington, D. C., February 12, 1936.

³That is, for the first time in the city from which the registration was reported. Approximately one-sixth of these new cases had received relief in some other city. See p. 13.

16 percent of the total urban population.⁴ If the number of persons admitted for the first time to relief, plus those readmitted in 1935, were proportionately as large for all the urban areas as for the 13 cities studied, then about 20 percent of the population of urban United States received relief at some time in 1935.

In summary, therefore, the total number of different persons receiving relief at some time in 1935 in the 13 cities was greater than the number actually on relief in December 1934, but the actual number of persons receiving relief or wage assistance was smaller at the end than at the beginning of the year. The decline in the number of persons receiving relief or wage assistance in the 13 cities was from 14.0 percent of the population in December 1934 to 12.5 percent in December 1935 (appendix table 2).

Proportion of Persons Receiving Relief or Wage Assistance

Proportion by Age Groups

The median age of all persons receiving aid was 24 years, while the median for the general population was 30 years. This difference of 6 years was due to the large number of children among families on relief. Children under 16 in cases receiving relief or wage assistance in December 1935 constituted almost a fifth of all children under 16 in the general population, whereas among other age groups the proportions of the population were considerably smaller. The proportion of the population receiving aid was somewhat smaller for the group 65 and over than for the group 45—64 years of age partly because of provisions for the aged through pensions and institutions.

Proportion by Sex

Approximately the same proportions of the men and women in the general population received aid at the beginning and end of 1935: about 14 percent of each sex received aid in December 1934 and 12.5 percent received aid in December 1935 (appendix table 2).

Proportion by Race

The proportion of the Negro population receiving aid was three times that of whites among all age groups under 65 years, both in December 1934 and in December 1935. Approximately a third of all Negroes and a ninth of all whites received aid at the beginning of the year, while for both races the proportions receiving aid were somewhat smaller at the end of the year. Among

⁴Urban relief population estimate of 11,400,000 persons as of December 1934 and total general population estimate of 71,000,000 as of January 1, 1935, made by Urban Estimates Section, Division of Social Research, Works Progress Administration, Washington, D. C.

Negroes about a half of the children under 16 years and almost a half of the age group 65 and over were on the rolls. The greater representation of Negro than of white population on relief was particularly marked in the age group 65 years and over, where the proportion of Negroes was five times that of whites. This racial difference may be attributed in the main to two factors. First, the resources upon which aged Negroes can draw are less than those of aged whites (appendix table 2). And second, unskilled persons—a predominant group among Negroes—find age a greater handicap in securing employment than do other occupational groups.

The proportion of Negroes first admitted to relief in 1935 was about twice that of whites for each age group except the group 65 and over. For this oldest group the proportion for Negroes was over three times that for whites (appendix table 1).

Proportion of Families Receiving Relief or Wage Assistance

*Proportion by Size of Family*⁵

The proportion of large families in the general population receiving aid was markedly greater than that of small families. Less than a seventh of all two-person families in the general population were on relief both in December 1934 and in December 1935. At the other extreme, the proportion of families of 10 persons or more was nearly a fourth at the beginning of the year and slightly over a fifth at the end (fig. 1 and appendix table 3).

Proportion of Experienced Workers Receiving Relief or Wage Assistance

Proportion by Socio-Economic Groups

In December 1934 about a tenth of all experienced workers in the 13 cities were receiving relief or wage assistance. The proportion was lowest in the white-collar group and highest in the unskilled group. In the latter group the proportion of

⁵The number of unattached individuals in the general population is not available from the reports of the U. S. Bureau of the Census. It is necessary, therefore, to exclude one-person cases and to limit the study of relief incidence by size of case to family cases.

Reports of the Census Bureau for 1930 show that 10 percent of the people in the 13 cities were either lodgers or members of so-called "quasi families," the latter consisting largely of people living in hotels and rooming houses. Inasmuch as census family data are reported only for the remaining 90 percent of the population, such family-size data are understatements of the number of families of various sizes in the general population.

While census data are not available on the distribution of lodgers and quasi families, by family units of various sizes, it is doubtless true that the bulk of them consists of the smaller units, especially one-person cases, and that the understatement of families in the general population, referred to in the preceding paragraph, is relatively greater in the families of small size than in the families of large size. It follows, therefore, that the proportion of small families receiving relief or wage assistance is overstated in fig. 1 to a greater extent than the proportion of large families.

FIG. 1- PROPORTION OF FAMILIES IN THE GENERAL POPULATION
RECEIVING RELIEF OR WAGE ASSISTANCE
BY SIZE OF CASE, 13 CITIES

Source: Table 3.

AF-3002, WPA

manual laborers receiving aid was considerably below that of domestic and personal service workers. The proportions for the different groups are shown in appendix table 4.

Approximately 2.1 percent of the experienced workers in the 13-city population received their first relief in 1935. Among the occupational groups the proportion was lowest for the white-collar group, and it was only slightly higher for skilled workers. This may be due in part to the greater resources upon which these groups can draw after losing their jobs. The proportions were considerably higher for semiskilled workers and for unskilled workers, the latter being the highest. Among unskilled workers the proportion of laborers receiving first relief in

1935 was considerably below that of domestic and personal service workers.⁶

Proportion by Usual Industry

The proportion of workers receiving aid in December 1934 was greater in the building industry than in other industries. The proportion was nearly as high in the domestic group and only slightly less in the food group.⁷ It was lowest in the trade group.

By far the greatest change during 1935 occurred in the automobile group, where the proportion of workers receiving aid dropped about a half in December 1935. The rapid revival in this industry and the early appearance of the 1936 automobile models undoubtedly were responsible (appendix table 5).

TRENDS OF THE RELIEF AND WAGE ASSISTANCE LOAD IN 13 CITIES DURING 1935

An increase or decrease in the number of cases receiving aid⁸ was, ingeneral, paralleled by a similar increase or decrease in the number of persons and of workers. But the amount of increase or decrease among these three groups was not always proportionate. For example, from December 1934 to December 1935 the relief and wage assistance case load declined 6 percent, the number of persons in these cases fell 11 percent, and the number of workers in receipt of aid declined 8 percent (appendix table 6).

Trend of Relief and Wage Assistance to Persons

Trend by Age Groups

The largest declines in the number of persons receiving aid were in the younger age groups. Between the beginning and end of 1935 the number of persons receiving aid in the three younger age groups (under 16, 16—24, and 25—44 years) declined between 12 and 13 percent. During the same period, however, the number of persons receiving aid in the age group 45—64 years declined only 5 percent and the number in the group 65 years of age and over remained about the same (appendix table 7).

These changes necessarily affected the age distribution of persons receiving aid. During the year two of the younger age groups (16—24 and 25—44 years) steadily declined in relative importance, while the two older age groups (45—64 and 65 years

⁶From unpublished data in the files of the Division of Research.

⁷The incidence of aid in the food group is considered larger than the food-group average for the country. This conclusion is based upon an examination of 1930 Census data showing that slaughtering and meat packing, which suffered severe employment declines in the latter part of 1934 and 1935, constitutes a far greater proportion of the food-group total for 13 cities than for the country as a whole.

⁸The terms *aid* and *relief and wage assistance* are used interchangeably throughout the report. By definition, they include all cases receiving either relief or having one or more members employed on the Works Program.

and over) increased in importance. The relative importance of the youngest age group (under 16) varied more from month to month but showed no significant tendency to permanent increase or decrease during the year (fig. 2 and appendix table 8). The probable explanation is that persons in all the age groups except the youngest (under 16) were capable of independent movement on and off relief. Children (under 16), however, necessarily moved on and off relief only as part of families whose other members were in age groups over 16 years. It would appear, therefore, that over a period of time changes in the age distribution of the relief population are least likely to occur in the age group under 16 years.

Trend by Sex

The relative declines in the number of men and women receiving relief or wage assistance were the same: each fell 11 percent. The declines in the age groups under 45 years, for each sex, were greater than the decline in the 45—64 group. In the oldest age group, 65 years and over, the number of men receiving relief or wage assistance rose nearly 2 percent during the year, while the number of women fell more than 2 percent (appendix table 7).

Trend by Race

The decline in the number of Negroes receiving aid was less than that of white persons.⁹ This was true within each age group except the group 65 and over.¹⁰ For each race the three younger age groups (under 16, 16—24, and 25—44 years) fell more than the older age groups (appendix table 9).

Trend of Relief and Wage Assistance to Cases

Trend by Size of Case

The average size of case declined very little during the year (appendix table 10). The relief and wage assistance load of family cases, following an insignificant rise from December 1934 to January 1935, declined steadily to July, at which time it was 8 percent below that of December 1934; at the end of the year it was still 5 percent below. There was a substantial drop in the number of cases with three or more persons. On the other hand, the nonfamily (or one-person) case load, after a decline during the summer months, rose during the balance of the year and by December 1935 was 8 percent above the level of December

⁹ Races other than white and Negro, comprising less than 2 percent of the persons receiving relief or wage assistance in the 13 cities, have been excluded from the race comparisons.

¹⁰ In June 1935 many unemployable cases in Atlanta were closed by transfer from the emergency relief administration to the department of public welfare. This caused many persons 65 years of age and over to leave the relief rolls. Exhaustion of funds of the local emergency relief administration in November resulted in additional separations of aged persons from relief.

FIG. 2 - TREND IN AGE DISTRIBUTION OF PERSONS RECEIVING
RELIEF OR WAGE ASSISTANCE, 13 CITIES
December 1934 - December 1935

Source: Table 8.

AF-3003, WPA

1934 (fig. 3 and appendix table 11). An increase in the total number of persons in one- and two-person cases was more than offset by the decline in the total number in cases of three persons or more. These factors caused the number of persons receiving relief or wage assistance to decline relatively more than the number of cases.

FIG. 3-TREND OF FAMILY AND NONFAMILY CASES RECEIVING RELIEF OR WAGE ASSISTANCE, 13 CITIES
December 1934 - December 1935

Source: Table 11

AF-3004, WPA

Trend of Relief and Wage Assistance to Cases With Workers and Cases Without Workers

About nine-tenths of the cases had one or more workers in the case.¹¹ These cases declined 7 percent during the year, while the number of cases without workers showed little change, declining less than 1 percent (appendix table 12).

Trend of Relief and Wage Assistance to Workers

Trend by Sex

About 70 percent of all workers were men, and about 30 percent were women. The number of male workers receiving aid declined 9 percent during the year, while the number of female workers declined 7 percent. The distribution of workers by sex at the end of 1935 showed little change from that at the beginning of the year (appendix table 13).

¹¹Workers are defined as persons between the ages of 16 and 64 years who are working or seeking work.

Trend by Race

During the year the number of white workers receiving relief or wage assistance declined 9 percent and the number of Negro workers declined 7 percent. In both December 1934 and December 1935 the relative proportions of each group in the total worker load remained practically the same: in both months white workers constituted about three-fourths and Negro workers about one-fourth of all workers receiving aid (appendix table 13).

Trend by Experience Status

Approximately nine-tenths of the cases had one or more workers 16—64 years of age who were either working or seeking work. In every 100 of these cases there were about 145 workers, of whom 22 were without previous work experience.¹²

Between December 1934 and December 1935 the number of inexperienced workers receiving aid declined 8.3 percent. Experienced workers showed close to the same proportionate decline (appendix table 13).

Trend by Socio-Economic Groups of Experienced Workers

Of all experienced workers receiving aid in December 1934, about a third were unskilled workers, another third were semi-skilled workers, a sixth were skilled, and the remaining sixth were white-collar workers. Each of these four major occupational groups receiving aid declined during the year but in different proportions. Skilled workers showed the greatest net decline (15.7 percent); then followed semiskilled workers (10.3 percent), unskilled workers (7.2 percent), and white-collar workers (1.5 percent) (appendix table 14).

Approximately two-thirds of the white-collar workers were former clerks. The remaining third had been proprietors and professional workers. During the year the number of clerks and professional workers receiving aid declined while the number of proprietors increased. Unskilled workers receiving aid were about equally divided between laborers and domestic and personal service workers. Each of these groups declined during the year.

During the year there was an increase in the relative importance of the white-collar group and a decrease in that of the skilled group. In the semiskilled and unskilled groups the marked seasonal changes make it difficult to make any statement concerning trends (fig. 4 and appendix table 15).

¹²In this study an inexperienced worker is defined as one who has not worked on a job for at least 1 day a week for 4 consecutive weeks sometime during the 10-year period prior to interview.

FIG. 4 - TREND IN OCCUPATIONAL DISTRIBUTION OF EXPERIENCED WORKERS RECEIVING RELIEF OR WAGE ASSISTANCE
13 CITIES

December 1934 - December 1935

Source. Table 15

AF-3005, WPA

Trend by Usual Industry of Experienced Workers

Wider variations occurred in the trends of industrial groups¹³ receiving aid than of occupational groups. The greatest variation in the occupational groups occurred between skilled workers and white-collar workers, where the spread between percentage declines was approximately 14 percent (appendix table 14). However, among the industrial groups the number of workers on relief that were usually employed in the automobile industry declined 49 percent during 1935 while the number in the food group increased 15 percent, making a spread of 64 percent between the two industrial groups (appendix table 16).

The basis for this greater variation in trend between industrial groups receiving aid than between occupational groups is found in the fact that during periods of business expansion improvement in the various industries is by no means uniform. Indeed, retrenchment frequently takes place in some industries, while large gains are being made in others. Generally speaking, adverse trends in a given industry cause workers from each of the major occupational groups to be laid off. At the same time, expansion in another industry results in separations from the relief rolls of workers in each of the major occupational groups. Thus, for a given occupational group favorable developments in one industry tend to offset less favorable or unfavorable developments in another. This offsetting tendency causes the occupational groups to show less fluctuation than the industrial groups receiving aid.

Despite the differences in fluctuations of the various industrial groups during the year, the importance of each group among the workers on relief did not change markedly between December 1934 and December 1935. Workers in the automobile industry showed the greatest change.

Trend of Employment by Industrial Groups and Numbers Receiving Aid

Evidence of the close relationship between employment and relief is found in a comparison of the number of workers receiving aid with the volume of employment, by industrial groups. Since employment data are not available for the 13 cities, employment estimates for the entire United States have been used. A comparison of relief and wage assistance loads in the 13 cities with estimated employment in the United States is subject to

¹³The present discussion is limited for the most part to seven industrial groups—building and construction, iron and steel, automobile factories and repair shops, food and allied industries, transportation and communication, retail and wholesale trade, and domestic and personal service. These 7 groups comprised three-fourths of all the experienced workers on relief in the 13 cities in December 1934; each of these groups contained 4 percent or more of the 13-city relief load at that time.

many limitations.¹⁴ Nevertheless, it is believed that such a comparison is sufficiently reliable to indicate the influence of employment changes upon relief and wage assistance trends.

Among the industrial groups there was a marked tendency for the number of workers receiving aid to decrease as employment increased and vice versa.¹⁵ This relationship between employment and the number receiving aid was especially striking in three of the seven industrial groups—automobiles, iron and steel, and building and construction. It was least evident in the food and trade groups.¹⁶ In the food group, however, it should be pointed out that activity in the canning industry, which is inadequately represented in the 13 cities, caused a marked rise in the employment index during the early fall. This rise had no counterpart in the 13-city relief load (fig. 5 and appendix table 17).

¹⁴First, the various industrial groups are not uniformly represented in the 13 cities; the degree of coverage ranges from 33.0 percent of urban United States in the case of automobile factories and repair shops to 5.9 percent in the case of mineral extraction. Second, for some of the industrial groups conditions in the 13 cities in 1935 were not fair measures of conditions throughout the country. For example, the textile industry suffered relatively more in the 13 cities than in the country at large. Third, the data serving as the basis for some of the employment estimates are known to be inadequate. Fourth, it should be noted that the number on relief in December 1934, the month used as the base for all relief-load trends, is an estimate in every instance and hence is subject to some margin of error. This means that percentage variations above or below December 1934 may be overstated or understated. However, the direction of the change—whether an increase or a decrease—is correctly shown.

¹⁵In comparing the trend of employable persons on relief with the trend of employment, it is important to note that a person who receives last relief at any time within a given month is not removed from the load until the following month. Thus, a person who secures a job on March 10 and receives his last relief grant the next day is included in the case-load figures for March but is not considered a part of the April case load unless he receives further relief in April. Having begun work by the middle of March, however, he is included in the March employment estimate. His job is first reflected in the employment estimate for March, but his separation from the relief rolls does not affect the load until April. For this reason case-load figures for one month should be compared, not with employment estimates for the same month but with estimates for the preceding month.

It is also true that some cases coming on relief lost their private employment and received a relief grant in the same calendar month. The number of such cases, however, was comparatively small. The 1935 data indicate that at the time of admission to relief only 24 percent of the workers in accessions were unemployed less than 1 month, and the median average duration of unemployment was about 3 months. Consequently, the relationship between loss of job and accession to relief is apt to be spread over several months.

In fig. 5 employment data are moved forward 1 month in all instances. November 1934 is taken as 100 percent for all employment series; December 1934, for all series of relief loads. December 1934 employment is plotted opposite the January 1935 relief load; January employment, opposite the February relief load; and so on.

¹⁶The 8 industrial groups receiving aid which are discussed here—building and construction, iron and steel, automobiles, transportation and communication, food, trade, domestic and personal service, and miscellaneous—include all experienced workers in the relief population of the 13 cities. Some of the employment estimates are those by Nathan, Robert R. in "Estimates of Unemployment in the United States, 1929—1935," *International Labour Review*, Vol. 33, No. 1, January 1936, extended through 1935; the others have been computed by using a method similar to that used by Mr. Nathan.

ACCESSION AND SEPARATION RATES OF PERSONS, CASES, AND WORKERS ON THE RELIEF ROLLS OF 13 CITIES DURING 1935

A comparison of the number of persons or cases receiving relief or wage assistance between December 1934 and December 1935 shows the change in the size of the relief load between the beginning and end of the year, but it does not show the extent of the month-to-month movement on and off relief. Moreover, the net change in the relief rolls as shown by the number under care in December 1934 and December 1935 understates the amount of change that went on within the relief population during the year. Thus, if 1,000 cases are added to the relief rolls in a given month and 2,000 are removed, the net effect upon the load is the same as though the accessions and separations were 11,000 and 12,000, respectively, or any other numbers differing by a like amount.

Between the beginning and end of the year the number of cases receiving relief or wage assistance in the survey cities declined on an average of one-half of 1 percent a month. During this same period, however, the average monthly separation rate approximated $5\frac{1}{2}$ percent of the case load while the average accession rate approximated 5 percent a month.¹⁷ Thus, the accession rate and the separation rate were each about 10 times as large as the net change in the relief case load.

Accessions to the relief rolls consist of new cases—i.e., cases new to relief in a given city—and of reopened cases—i.e., cases which have been on relief at least once before. More than two-fifths of the total accessions were cases that had never received relief in their respective cities. Approximately a sixth of these had a prior relief history in some other city. Therefore, if the proportion of new cases (44 percent) in accessions is reduced by a sixth to account for those new cases that had received relief at some time in another city, it is apparent that somewhat more than a third of all cases admitted to relief in the survey cities during the year had received no previous relief. During the course of the year the proportion of new cases in total accessions decreased slightly (appendix table 18).

¹⁷ Accession and separation rates are computed by expressing the volume of accessions and of separations as percentages of the total number of cases receiving relief some time during the month. Since a case is considered closed in the month following that in which last relief was received, the separations of a given month may be regarded as applicable to the preceding month's load. Similarly, the accessions of a given month may also be thought of as applicable to the load of the preceding month. For this reason, in computing the separation and accession rates for a given month, the number of cases receiving relief some time during the preceding month has been used as the base. Computed in this way, a given month's accession rate minus its separation rate is the percent change in the load from the preceding month. Separation rates used throughout this report include all separations from the relief rolls except those for Works Program employment. Works Program closings have not been included because they are in the nature of a transfer of the relief load from one agency to another.

FIG. 5 - TREND OF EMPLOYMENT IN THE UNITED STATES AND OF EXPERIENCED WORKERS RECEIVING RELIEF OR WAGE ASSISTANCE, BY USUAL INDUSTRIAL GROUPS
13 CITIES — Continued

December 1934 — December 1935

Note: For employment, November 1934 = 100 %;
for relief and wage assistance, December 1934 = 100 %.
All employment data moved forward 1 month.

This group of new cases with no prior relief comprised about 6,700 cases a month in the 13 cities. The total relief population of these cities was approximately a tenth of the relief population of urban United States. A rough estimate, therefore, indicates that about 67,000 new cases were added each month during 1935 to urban relief rolls in the United States; this occurred despite the fact that 1935 was, on the whole, a year of economic recovery.

The turnover of persons and workers in the relief population was quite similar to that of cases. The turnover of persons was slightly less than that of cases because of the comparatively low accession and separation rates for large families (appendix table 19).

Accession and Separation Rates for Persons

Accession and Separation Rates by Age Groups

The average monthly accession rate for all persons on relief during the year was 4.3 percent; the separation rate was 5.3 percent. Of the different age groups persons 25—44 years old showed the highest turnover; the most employable group of workers in the relief population is to be found in this age group. The turnover of persons in the age group 65 years and over was considerably below the general average; the accession and separation rates approximated four-fifths and three-fifths, respectively, of those for the group 25—44 years of age (appendix table 20).

Accession and Separation Rates by Sex

The movement on and off relief of men 25—44 years of age was a fourth higher than that of women in this age group. The average monthly turnover, however, was only a tenth greater for all men than for all women. The turnover for men was highest in the group 25—44 years, while that for women was highest in the age group 16—24 years (appendix table 20).

Accession and Separation Rates by Race

Average monthly turnover of Negro persons on relief was considerably smaller than that of white persons. This was true of all age groups and of both sexes. The average monthly accession rate for Negroes was 2.7 percent as compared with 4.9 percent for whites. Average monthly separation rates were 3.4 percent for Negroes and 6.0 percent for whites. For both whites and Negroes maximum turnover occurred in the age group 25—44. Minimum turnover occurred in the youngest and the oldest age groups (appendix table 20).

Accession and Separation Rates of Cases

Accession and Separation Rates by Size of Case

In general, the larger the case, the lower was the turnover. Accession and separation rates of one-person cases considerably exceeded the rates of other case sizes. Outside of the one-person cases differences in the rates by case size were less pronounced (appendix table 21).

Accession and Separation Rates of Cases With Workers and Cases Without Workers

Notwithstanding the absence of workers, monthly separation rates of cases without workers were approximately two-thirds those of cases with workers. Cases without workers had an average monthly accession rate of 3.8 percent; those with workers, 5.2 percent. The average monthly separation rate of cases without workers was 3.9 percent; of cases with workers, 5.8 percent.¹⁸

Accession and Separation Rates of Workers

Accession and Separation Rates by Race and Sex

The turnover of Negro workers was approximately two-thirds that of white workers. Accession and separation rates for female workers of all races combined approximated four-fifths those for male workers. By sex and race, accession and separation rates were definitely lower for male and female Negro workers than corresponding rates for white workers (appendix table 22).

Accession and Separation Rates by Experience Status

Turnover of inexperienced workers approximated three-fourths that of experienced workers. The average monthly accession rate of inexperienced workers was 3.5 percent; that of experienced workers, 5.1 percent. The average monthly separation rate of inexperienced workers was 4.3 percent; that of experienced workers, 5.9 percent. Only a small part of the separations from relief of inexperienced workers can be attributed to their own private employment; most of these workers were young persons who left the relief rolls because some experienced worker in the case was able to secure employment.

Accession and Separation Rates by Socio-Economic Groups of Experienced Workers

Among experienced workers average monthly accession and separation rates were highest for skilled and semiskilled workers and lowest for white-collar and unskilled workers. In the white-collar subgroups turnover was lowest in the clerical group.

¹⁸From unpublished data in the files of the Division of Research.

Among unskilled workers accession and separation rates of domestic and personal service workers were considerably below those of manual laborers (appendix table 23).

Accession and Separation Rates by Usual Industry of Experienced Workers

Average monthly relief accession and separation rates of experienced workers from the automobile industry were higher in 1935 than those of any other industrial group. The separation rate of this group was almost double the accession rate. Improvement in the iron and steel industry also caused the separation rate of that industrial group to exceed the accession rate by a wide margin. Adverse employment trends in the food industry, on the other hand, made the accession rate of this group higher than the separation rate (appendix tables 24 and 25).

Seasonal changes of employment in the various industries were reflected in monthly fluctuations of accession and separation rates. Thus, among building workers relief accession rates were highest during the winter and fall and separation rates were highest during the spring and summer. In the automobile group relief accession rates were highest during the summer slack; separation rates were highest in the fall and winter busy season.

REASONS FOR OPENING AND CLOSING RELIEF CASES IN 13 CITIES
DURING 1935

The majority of the relief case accessions and separations in the survey cities during 1935 were caused by loss or gain of private employment. During the last 10 months of the year slightly more than a half of total accessions were caused by loss of job less than 4 months prior to receipt of the first relief grant; 6.5 percent were caused by decreased hours of work or rate of pay; and 14.1 percent were caused by loss or depletion of resources (appendix tables 26, 27, and 28).

Corresponding reasons for removing cases from the relief rolls include employment secured in private industry and increased hours of work or rate of pay. These reasons were responsible for 50.8 percent and 7.0 percent, respectively, of total regular closings¹⁹ (appendix table 29). In addition, a substantial number of the cases were closed because of failure to report to the agency granting relief; many of these cases actually had members in private employment at the time the case was closed.²⁰ This nonreporting group represents about a seventh of the separations throughout a 10-month period. When some allowance is

¹⁹Regular closings include all relief closings except those for Works Program employment.

²⁰See p. 19.

made for this fact, it appears that between 60 and 70 percent of all accessions and separations were caused by changes in employment status.

Available data for the last 5 months of the year indicate that loss of aid from friends and relatives ranked next in importance to changes in employment status as a reason for opening cases, accounting for about a sixth of total accessions. Administrative policy, discharges from institutions, transfers from other public and private relief agencies, and miscellaneous other reasons accounted for less than a tenth of the openings.

Receipt of aid from friends and relatives ranked second in importance to employment in private industry as a reason for closing relief cases. Income from sources outside the case, such as discovery of unrealized assets and financial aid, ranked third.

Reasons for Opening and Closing Family and Nonfamily Relief Cases

Loss of employment, which was the principal factor responsible for the opening of both family and nonfamily cases during the last 10 months of the year, was more important for family than for nonfamily cases. The three reasons directly related to employment—loss of private employment within 4 months, decreased hours of work or rate of pay, and loss or depletion of resources—accounted for an average of 82 percent of the family and 63 percent of the nonfamily openings.

Family cases applied for relief sooner after loss of private employment than did nonfamily cases. Loss of job within 4 months was a more important reason for the accession of family than of nonfamily cases. On the other hand, loss or depletion of resources and loss of aid from friends and relatives accounted for greater proportions of total openings for nonfamily than for family cases (figs. 6 and 7 and appendix tables 30 and 31).

Comparison of the reasons for closing family and nonfamily cases is difficult because of a large client-failed-to-report category in the nonfamily group. For family cases employment in private industry combined with increased hours of work or pay accounted for nearly three-fourths of all separations during the last 10 months of the year. The corresponding proportion for nonfamily cases was only one-fourth. However, it is not improbable that many of the separations in the client-failed-to-report category were caused by private employment.²¹ While

²¹Two facts may be cited as evidence that the client-failed-to-report category contains a considerable number of private-employment closings. In the first place, more than 70 percent of the nonfamily closed cases are males between the ages 25–44 years, inclusive, divided about equally between those under and those over 44 years of age. Nonfamily persons—largely able-bodied men with few or no dependents—are able to move about freely in search of employment opportunities and to accept employment away from their homes. In the second place, because of lesser mobility and greater continuous need of assistance, family cases tend to maintain closer contact with the relief agency than do nonfamily cases and hence are more apt to report their employment status.

FIG. 6 - REASON FOR OPENING FAMILY AND NONFAMILY RELIEF CASES, 13 CITIES

Source: Table 31.

this category (client-failed-to-report) accounted for only 5 percent of all family case separations, it accounted for 34 percent of the nonfamily case separations.

A detailed analysis of reasons for separation not directly associated with employment is available only for the last 5 months of the year. The proportion of nonfamily cases closed for reasons not directly associated with employment status was at least twice that of family cases.

Reasons for Opening and Closing White and Negro Relief Cases

Loss or decrease of employment—the principal reason for opening cases—accounted for over three-fourths of the accessions of white cases but less than two-thirds of the Negro cases. On the other hand, loss of aid from friends and relatives was responsible for only about a seventh of all white cases but over a fourth of all Negro cases admitted to relief during the last 5 months of the year²² (appendix tables 26, 27, and 28).

Among relief cases closed, the percentage of separations from relief because of jobs secured in private industry and increased hours or pay was a third higher for white cases than for Negro cases, but receipt of aid from friends and relatives caused less than half as many closings among whites as among Negroes²³ (appendix table 29).

Reasons for Closing Cases Without Workers

Data pertaining to reasons for closing cases without workers were obtained only for May and October 1935. More than three-fifths of these closings in both months were due to aid from friends and relatives, outside sources of income, transfers to other agencies and institutions, and death. A small proportion of the closings—about a sixteenth in both months—was attributable to private employment.²⁴ Between these months there was

²²Detailed tabulations of "other reasons" were made only for the last 5 months of 1935.

²³Another racial difference is to be found in the closing of relief cases because of "expectancy of Works Program employment." While this reason accounted for less than 1 percent of the white cases closed, it accounted for 12 percent of the Negro cases closed. Examination of individual city data shows that only one city—Atlanta—reported this item among the reasons for closing; it occurred for the most part in November when, on the 15th, the emergency relief administration in Atlanta closed its doors because of complete exhaustion of funds. Subsequent to November 15 relief was administered in Atlanta by the Fulton County Department of Public Welfare. Because of shortage of funds, many Atlanta cases on the active relief rolls in October received no relief in November. According to the definition of a closing, it was necessary to regard such cases as closed in November, unless they had already been closed because of Works Program employment. In a number of instances efforts to place them on the Program had failed up to November 30 and expectancy of Works Program employment was assigned as the reason for closing.

²⁴Workers are defined as persons between the ages 16 and 64 years who are working or seeking work. In a few instances persons outside the age group 16—64 years were able to secure Works Program employment or sufficient private employment to close their cases.

a sharp drop in outside sources of income as a reason for closing and a large increase in transfers to agencies or institutions.

In both months outside sources of income and private employment were considerably more important as reasons for closing white cases without workers than Negro cases. On the other hand, the proportion of closings because of aid from relatives and friends and death was larger for Negro than for white cases (appendix table 32).

OCCUPATIONAL AND INDUSTRIAL SHIFTS OF EXPERIENCED WORKERS EMPLOYED AT TIME OF CLOSING IN 13 CITIES DURING 1935

Inexperienced Workers With Jobs at Closing

Inexperienced workers comprised less than an eighth of all workers in regular closings²⁵ during the last 6 months of the year (appendix table 33). Of this one-eighth only a very small proportion had private jobs at time of closing. On the other hand, about three-fifths of the experienced workers in regular closings had private employment. Because of the very small number of employed inexperienced workers, the discussion of occupational and industrial shifts which follows is limited to experienced workers employed at the time their relief cases were closed.

Occupational Shifts

Regardless of their usual occupations, many workers on relief took whatever nonrelief jobs there were available. Data obtained for the last 6 months of the year indicate the extent to which experienced workers from the relief rolls secured private employment at their usual occupational levels. There were insufficient jobs to absorb all the employed white-collar, skilled, and semiskilled groups at their usual occupations. About a fifth of these workers had to accept jobs outside their usual occupational employment. For example, skilled workers made up 17.5 percent of all those employed at closing, but only 14.8 percent of all jobs held were in the skilled category. This suggests that opportunities to shift into skilled jobs were small and that skilled workers succeeded in obtaining work at other occupations. What has been said of the skilled worker also applies to the white-collar and semiskilled but to a much lesser extent. As a result of this crowding by other groups, the unskilled worker found himself at a disadvantage in competing for jobs in private industry (appendix table 34).

The displacement of unskilled workers by those in more skilled groups was limited largely to white workers. Most of the crowding of the unskilled group came from the white-collar and skilled

²⁵By definition, a regular closing is any relief case closing except one having Works Program employment.

groups. Among Negroes these two latter groups constituted only about a tenth of the total employed at time of closing. Among whites, however, the white-collar and skilled workers accounted for over a third of all workers employed at closing.

The greatest proportionate shift occurred out of the skilled workers' group. About three-tenths of all workers employed at closing whose usual occupations were in the skilled category held jobs outside the skilled group. The corresponding shifts out of other groups were only slightly less for white-collar workers: the shift was about a fifth for semiskilled workers and only about an eighth for unskilled workers (appendix table 35).

About a third of those who shifted moved upward, and the remaining two-thirds moved downward.²⁸ About a sixth of the skilled workers who shifted moved upward into the white-collar group. The remainder that shifted downward were about equally divided between semiskilled and unskilled jobs. Among those usually employed at white-collar occupations, about a seventh of those who shifted went into skilled work; the remainder held semiskilled and unskilled jobs in about equal proportions. Of the semiskilled workers who shifted, approximately three-fifths moved downward into the unskilled group, while those who moved upward were divided about equally between white-collar and skilled work. The majority of unskilled workers who shifted upward were absorbed in the semiskilled group.

The proportionate shift out of each occupational group was greater for Negroes than for whites, except in the unskilled category. Also, as might be expected, the proportionate downward shift of white-collar, skilled, and semiskilled workers was much greater for Negroes than for whites. Likewise, the upward shift of Negroes was smaller than that for whites.

Industrial Shifts

The usual industry of employed workers in closed cases was about the same as that of workers in the relief population as a whole. Moreover, the jobs held at the time of closing were distributed among the various industries in about the same proportion as workers in the relief load. To illustrate, 5.9 percent of the workers receiving relief during the months June through September 1935 reported iron and steel as the industry of usual employment; 5.9 percent of the workers who were employed at the time their cases were closed usually worked in the iron and steel group; and 6.0 percent reported having jobs in the iron and steel industry. The widest differences occurred in

²⁸ In this report occupational groups are ranked in the following order: white-collar, skilled, semiskilled, and unskilled. Movement in the direction of the unskilled group is termed a *downward shift*. Conversely, movement in the direction of the white-collar group is termed an *upward shift*.

the automobile, domestic and personal service, and miscellaneous groups (appendix table 36).

Among the major industrial groups slightly more than a fourth of the workers shifted to jobs outside the industry of their usual employment. At the one extreme, nearly two-fifths of the group usually employed in transportation and communication shifted to other industries. At the other extreme, only about a seventh of the workers usually employed in the domestic and personal service group moved to other industries (appendix tables 37 and 38). No attempt has been made to measure the shift from one kind of work to another within a given industry.

Negroes evidently encountered greater difficulty than whites in finding work outside the industry in which they had usually been employed. Among employed white workers over a fourth were outside their usual industry; the corresponding proportion for Negroes was only about a fifth (appendix table 37).

SUPPLEMENTATION OF PRIVATE-EMPLOYMENT EARNINGS WITH RELIEF IN 13 CITIES DURING 1935

In addition to the cases which were wholly dependent upon direct relief in 1935, there were cases in which one or more workers were employed part time or full time in private industry. Their earnings were so low, however, that it was necessary to grant relief to these cases.

Proportion of Relief Cases Having Private-Employment Earnings

Less than a seventh of the cases on relief throughout May 1935 received nonrelief earnings. Among cases coming on relief in 1935, the proportion having private-employment income during the month of admission to relief declined in importance during the year (appendix table 39). Supplementation was more prevalent in reopened and large cases than in new and small cases. Since reopened cases were larger than new cases, the difference in supplementation of new and reopened cases amounted largely to a case-size difference. Supplementation was more common in Negro cases than in white cases, which cannot be explained by the size of the case but rather by the more extensive part-time employment among Negroes than among whites (appendix table 39).

Differences in supplementation among small and large cases are also available for 12 of the 13 survey cities in May 1934.²⁷ The May 1935 proportion of cases with private employment was smaller for each case size than the May 1934 proportion (appendix table 40). A part of this decline was doubtless caused by

²⁷ May 1934 data for 12 of the 13 survey cities was obtained from unpublished source tables of the published study by Palmer, Gladys L. and Wood, Katherine D., *Urban Workers on Relief*, Part I—The Occupational Characteristics of Workers on Relief in Urban Areas May 1934, Research Monograph IV, Division of Social Research, Works Progress Administration, Washington, D. C., 1936. Omaha was not included in this study.

an FERA ruling, issued on September 18, 1934, against supplementing the full-time earnings of workers employed in private industry. However, a difference between the 1934 and the 1935 data should be noted: A small number of closed cases are included in the May 1934 study, perhaps causing a slight overstatement of the extent of supplementation, whereas the May 1935 study is limited to cases on relief throughout the month.

Income of Supplemented and Nonsupplemented Relief Cases

The average relief benefit to supplemented cases on relief throughout the month of May 1935 was about three-fourths that of nonsupplemented cases (appendix table 41). Private-employment income in these cases was almost as large as the average relief benefit, but one-third of these private earnings was offset by reduced relief. The combined nonrelief earnings and relief income of supplemented cases averaged one and a halftimes the relief income of nonsupplemented cases, so that two-thirds of the private earnings accrued to the case as additional income (appendix tables 42 and 43).

It may be questioned why relief benefits were not reduced by the total of the income from private employment. This was not done for several reasons. First, because of the job there were outlays for lunches, transportation, and clothing which made increased allowances necessary for these budget items. Second, there were many instances in which the employed workers were the older children in their respective families, and in order to keep them from leaving home, they were often allowed to retain a considerable portion of their earnings for personal use. Third, unless the worker on relief received some monetary benefit as a result of the job, he might have been discouraged from taking it.

Characteristics of Workers in Supplemented Cases

*Employed Workers in Cases Admitted to Relief by Sex and Race*²⁸

The proportion of women having private employment was about twice that of men in both white and Negro cases coming on relief. The proportion of all Negroes having private employment was somewhat greater than the proportion of all whites, which may be accounted for by the preponderance of servants among Negro women and the low earnings through part-time employment of the servant group (appendix table 44).

²⁸ Some persons were considered employed when admitted to relief, though they were not actually working. For the most part, these persons were temporarily idle as a result of strikes or illness. They constituted approximately 1 percent of the experienced employable persons in the 1935 relief accessions in the 13 cities.

*Occupational Distribution of Jobs Held*²⁹

One-fifth of all workers employed while on relief in May 1934 in 12 of the survey cities held white-collar jobs; almost one-third held semiskilled jobs; more than one-third were engaged in unskilled work; and only one-eighth were in skilled work. Servants alone, in the unskilled group, accounted for almost one-fourth of the total workers in all supplemented cases in May 1934. Occupational distributions of jobs held by persons admitted to relief in 1935 in all of the survey cities and of employed persons in the May 1934 load in 12 of these cities are shown in appendix table 45.

The occupational distribution for employed whites was about the same as that for all workers employed at time of admission to relief. But for employed Negroes coming on relief, jobs were heavily concentrated in the unskilled category: two-thirds were engaged in unskilled work; and the servant classification alone accounted for one-half of the jobs held by this group.

Industrial Distribution of Jobs Held

About one-fourth of all workers employed while on relief in May 1934, in 12 of the survey cities, were in domestic and personal service; almost one-fifth were in trade; and one-fourth were in 5 industries combined—building and construction, iron and steel, automobile, transportation and communication, and food and allied industries. The other third were employed in miscellaneous industries. The industrial distributions of jobs held by persons admitted to relief in 1935 in the survey cities and by employed persons in the May 1934 relief load in 12 cities are shown in appendix table 46.

Wide differences exist between the industrial distributions of jobs held by whites and those held by Negroes at the time of admission to the relief rolls in 1935. More than a half of the Negroes were employed in domestic and personal service, while less than a fifth of the whites were employed in work of that kind.

UNEMPLOYMENT DURATION AND REEMPLOYMENT IN 13 CITIES DURING 1935

Reemployment opportunities for workers on relief varied with their experience, age, sex, race, occupational background, and duration of unemployment. The experienced workers on relief obtained self-supporting jobs during the latter part of 1935 at

²⁹Data on jobs held by employed persons in the relief load are not available for 1935. However, May 1934 data are available for 12 of the 13 survey cities and for 79 cities and also for relief accessions in the 13 cities during 1935.

a rate four times that of inexperienced workers.³⁰ Among the experienced workers on relief reemployment rates were much higher for workers in the younger age groups than for workers in the older age groups; they were much higher for men than women, for whites than Negroes, and for skilled and semiskilled workers than for white-collar and unskilled workers.

Duration of unemployment had a greater bearing upon chances for reemployment than any other factor.³¹ The reemployment rate of workers who had been unemployed less than 6 months was 12 times that of persons who had been out of work 2 years or more. Inasmuch as experienced workers unemployed 2 years or more constituted almost half of the experienced workers on relief, it is obvious that chances of reemployment were seriously restricted for a large number on the relief rolls.

Duration of Unemployment for Workers Upon Admission to Relief

About half of the experienced workers admitted to relief during 1935 in the survey cities had been unemployed less than 3 months; about a fourth had been unemployed for a year or more (appendix table 47); and workers in new relief cases, admitted between February and May 1935, had been unemployed for longer periods than those in reopened cases. Workers in new cases, because of greater resources, had been able to support themselves for longer periods after losing employment than had those in reopened cases.

Unemployment Duration by Age, Sex, and Race

Unemployment data relative to age, sex, and race of workers at time of admission to the relief rolls are available for February through May 1935. Resources upon which younger workers could draw were generally smaller than those of older people, and they consequently came on relief sooner after losing employment than did the older workers. The average duration of unemployment was higher for the age group 16—24 years than for any other group under 55 years. But for age groups above 24 years the average increased with age, beginning at 2.8 months for those 25—34 years and reaching 5.0 months for those 55—64 years (appendix table 48).

Women workers admitted to the relief rolls had been without work for much longer periods than had men. In only one age group (55—64) did the average unemployment period for men exceed that for women. A partial explanation is that women frequently

³⁰Inexperienced workers are those who have not held a nonrelief job lasting 4 weeks or more during the last 10 years.

³¹Duration of unemployment has been computed from the time of last nonrelief job of 4 weeks or more. The period includes unemployment both before and after coming on relief. The data are necessarily limited to experienced workers.

did not seek employment until the head of the family lost his job. Consequently, they may have been without gainful work for long periods, although they had been seeking employment for only a short time.

Negroes and whites were unemployed about the same length of time. One would expect the period to have been shorter for whites, because of their greater resources, but an offsetting factor was that proportionately more Negroes than whites were supported by friends and relatives before coming on relief.

Unemployment Duration by Occupational Groups

The white-collar workers remained off relief for longer periods after loss of employment than did the skilled, semiskilled, or unskilled workers (appendix table 49). One might expect that unskilled workers would have the shortest period of unemployment prior to coming on relief, but their average period was actually longer than that for skilled and semiskilled workers, whose periods of unemployment averaged the same. Unskilled workers had better opportunities, however, than those in the other groups to secure employment at casual jobs—jobs lasting less than 4 weeks and therefore considered insufficient in this study to terminate the period of unemployment—and the income from these jobs tended to prolong the period of unemployment prior to acceptance of relief.

Duration of Unemployment for Workers at Time of Separation From Relief³²

Workers leaving the relief rolls during the last 3 months of 1935 in regular closings had been unemployed on an average of about 8 months, while those in Works Program closings had been unemployed over three times as long. This would indicate that persons with short periods of unemployment were more readily reabsorbed into private employment than were persons with long periods of unemployment (fig. 8 and appendix tables 50 and 51).

Unemployment Duration by Age, Sex, and Race

Workers in the younger age groups, in both regular and Works Program closings, had been unemployed for much shorter periods, on the average, than had workers in the older age groups. However, the period of unemployment was much longer for workers in each age group in Works Program closings than for those in corresponding age groups in regular closings. The periods ranged from 12 months to 34 months for workers in Works Program closings and from 7 to 14 months for those in regular closings (appendix table 51).

In Works Program closings women had periods of unemployment somewhat shorter than those of men, but in regular closings

³²Workers employed for at least 4 weeks prior to closing are not considered.

FIG. 8—DURATION OF UNEMPLOYMENT OF WORKERS SECURING JOBS
AT CLOSING, REGULAR AND WORKS PROGRAM CLOSINGS
13 CITIES

October 1935–December 1935

Note: For duration intervals exceeding 3 months, the height of a given point has been obtained by reducing the percent of workers in the given duration interval to a 3 months' average centering at the given point. Presentation in this manner is necessary because of the irregularity of the duration intervals in the data.

Source: Table 50.

AF-3009, WPA

their unemployment duration was more than double that of men. Workers of each sex in regular closings, though, had been on relief for a much shorter time than those in Works Program closings. The difference in unemployment duration between men and women, as pointed out in the discussion of accessions, is due in part to the fact that women frequently do not seek employment until the head of the family loses his job and that they had been without gainful employment for long periods prior to seeking work (appendix table 51).

Whites and Negroes in Works Program closings had both been unemployed, on an average, slightly over 2 years. In regular closings, however, the unemployment period for Negroes averaged more than twice that for whites, but for both races the median duration of unemployment was much lower than that for workers in Works Program closings (appendix table 52).

*Unemployment Duration for Workers Securing Works Program
Employment or Private Employment*

About 55 percent of the experienced workers in regular closings secured jobs in private employment (appendix table 55). The average unemployment duration of the workers securing jobs was considerably less than that of all workers in these cases. Regular closings were heavily weighted with workers of comparatively short unemployment periods, and those with the shortest period had the best chances of reemployment. Comparisons by sex, race, and age groups also reveal marked differences (appendix table 53).

Slightly over a half of those who secured private jobs had been unemployed less than 6 months; only a ninth of the experienced workers assigned to Works Program jobs had been idle less than 6 months. Only about a seventh of those who obtained private employment had been without work 2 years or more, whereas approximately a half of the Works Program group had been idle for a like period (appendix table 54).

Although reemployment opportunities within a given group are best for those workers having a short unemployment period, caution must be exercised in drawing conclusions simply by comparing the unemployment duration of one group of workers with that of another group. Average duration of unemployment in some instances is not a valid measure of relative reemployment opportunities. In group comparisons it is possible for poor employment opportunities to be associated with short unemployment periods and good employment opportunities with long unemployment periods. For example, recent loss of jobs resulting in heavy relief accessions of one group of workers may cause the average duration of unemployment for that group to be relatively short. For another group good employment opportunities may result in few relief accessions and the removal from the relief rolls of

large numbers of short-time unemployed. Under these conditions the average duration of unemployment for the group remaining on relief would be relatively long.

Separation Rates of Workers on Relief

Data on employment status at closing for workers leaving relief rolls are available for the 13 cities during the last 3 months of 1935. About 50 percent of all workers in regular closings secured private jobs at time of closing,³³ 11 percent were already privately employed while still on relief,³⁴ and 34 percent were unemployed. The employment status at closing was unknown for the remaining 5 percent (appendix table 55).

Separation Rates of Workers by Age, Sex, and Race

Workers in the younger age groups showed higher average monthly separation rates than those in the older groups, and those in the younger groups, above 16—19 years, found it easier to secure private employment than did older workers (appendix table 55).³⁵

Male workers left the relief rolls at a higher rate than did female workers. Among those workers who left relief, more men than women were able to secure jobs at time of closing.

The separation rate was higher for white workers than for Negro workers, and jobs were more readily secured at time of closing by whites than by Negroes (appendix table 56).

Separation Rates of Inexperienced Workers

Inexperienced workers, approximating a seventh of the workers on relief, were largely young persons between 16 and 25 years of age. Men and women were about equal in number in this young group, but among those who were over 25 years women greatly outnumbered men (appendix table 58).

The separation rate of inexperienced workers was about three-fourths that of experienced workers and was highest for the group 16—19 years (appendix table 55). But some four-fifths of all inexperienced workers in closings left relief without jobs as against only one-fourth of the experienced workers. Some young workers were, of course, often taken off relief through the closing of cases by the employment of experienced workers.

³³Includes all workers obtaining self-supporting private jobs during the last 4 weeks on relief. All but a small proportion of the workers reported as securing jobs obtained sufficient income to close their cases. Examination of the data shows that the number of employable persons securing jobs during the last 4 weeks on relief exceeded the number of employable cases closed because of private employment by approximately 3 percent.

³⁴Workers employed at private jobs while still on relief for at least 4 weeks prior to closing.

³⁵The monthly separation rate is the number of workers leaving the relief rolls for every 100 workers receiving relief. For a more complete statement see p. 13, footnote 17.

Separation Rates of Experienced Workers by Occupational Groups

During the last 3 months of 1935 the separation rates were highest for semiskilled workers and lowest for white-collar workers; in the other two groups the rate was higher for skilled workers than for unskilled. But the proportion of workers in closings who secured self-supporting private employment was highest for skilled workers (appendix table 57).

Separation Rates of Experienced Workers by Duration of Unemployment

Experienced workers unemployed for a short time had the best chance of leaving the relief rolls. Furthermore, the great bulk of workers leaving relief after short periods of idleness secured self-supporting jobs. But the majority of those who left relief after long periods of idleness did so for reasons other than their own private employment (appendix tables 59 and 60).

Reemployment Rates of Experienced Workers on Relief

Wide differences existed in reemployment rates by duration of unemployment.³⁶ Workers idle for only 3 to 4 months secured self-supporting jobs in private industry at a rate of about 14 percent a month. But reemployment opportunities decreased rapidly as the unemployment period increased, until workers idle 2 years or longer had very small chance of leaving relief through private employment (fig. 9 and appendix table 61). Since one-half of the workers on relief had been unemployed 2 years or more, the significance of this is apparent.

Reemployment Rates by Age, Sex, and Race

Reemployment rates were highest in the age group 25—34 years and decreased with each successive age group unemployed any specified length of time. The older groups had much larger proportions of long-time unemployed than did the younger groups and were therefore doubly handicapped in their search for reemployment (appendix tables 61 and 62).

A study of the May 1934 urban relief population revealed that women had been unemployed for shorter periods than men.³⁷ The

³⁶By definition of a regular closing, the last month of relief is the month preceding that of closing. Consequently, October—December private-employment closings corresponded to jobs secured in September—November. The monthly reemployment rate is the number of experienced workers securing self-supporting private jobs at closing for every 100 unemployed experienced workers on relief.

³⁷Palmer, Gladys L. and Wood, Katherine D., *Urban Workers on Relief*, Part I—The Occupational Characteristics of Workers on Relief in Urban Areas May 1934, Research Monograph IV, Division of Social Research, Works Progress Administration, Washington, D. C., 1936, p. 44.

FIG. 9 - AVERAGE MONTHLY REEMPLOYMENT RATE OF EXPERIENCED WORKERS ON RELIEF, BY DURATION OF UNEMPLOYMENT
13 CITIES

October 1935 — December 1935

Source: Table 61.

AF-3010, WPA

same situation prevailed for workers on relief in the 13 cities during the last 3 months of 1935. It was also discovered that women workers on relief in the survey cities secured self-supporting jobs at a rate only a third that of men (appendix table 63). On the other hand, studies of workers in the general population have shown that displaced women found it easier to obtain jobs than displaced men but suffered greater income losses.³⁸ This difference may be due to the fact that the reemployment rate used in the present study was limited to relief workers who secured jobs yielding enough income to close their cases. Similar limitations were not imposed in connection with the studies of the general population.

Negroes and whites on relief had been unemployed about the same average periods. Half of each race were jobless 2 years or more, but the rate at which whites—both males and females—obtained self-supporting jobs at closing was more than double that of Negroes. Irrespective of sex, white and Negro workers with short unemployment periods had a much better chance of reemployment than those who had been without work for comparatively long periods (appendix table 63).

³⁸ Weintraub, David and Posner, Harold L., *Unemployment and Increasing Productivity*, National Research Project, Works Progress Administration, Washington, D. C., 1937, p. 74.

Reemployment Rates by Occupational Groups

Workers in the four occupational groups differed considerably in their reemployment rates. Semiskilled workers were reemployed at a rate slightly above that of the skilled group and at a much greater rate than that of the unskilled and the white-collar groups (appendix table 64). This advantage for the semiskilled workers was caused largely by seasonal improvement in the automobile industry during the fall of 1935. Then, too, both semiskilled and skilled workers obtained work outside their occupational levels in greater numbers than did the unskilled and white-collar workers. This meant that they moved up or down in the occupational scale and filled jobs in the white-collar and unskilled levels. The disadvantage of the white-collar workers in reemployment opportunity may also be accounted for by the fact that even though they are discharged later in a depression, they are not rehired as soon as workers in the other groups. Within each occupational group, however, workers unemployed for a short time had the best chance of reemployment (appendix table 65).

THE ROLE OF THE WORKS PROGRAM

Relief grants under the Federal Emergency Relief Administration, created in 1933, were made on the basis of need. The amount of relief granted to a case was based upon its budgetary requirements and its income, if any, from outside sources. The difference between the budgetary requirements and the allowance made for outside income determined the amount of relief to be granted. Frequently, however, the actual relief grant fell below this amount because of a shortage of agency funds.

With the introduction of the Works Program in the latter part of 1935, the security wage³⁹ was substituted for the principle of budgetary deficiency. The security wage did not vary with the size of the case, as had the relief grant, but was predetermined to take account of the occupational classification of the job and the geographical area in which the work was done. It was, then, in the form of a monthly salary and was generally higher than the former relief grant; the majority of the relief cases transferred to the Works Program benefited substantially from the transfer.

The number of persons unemployed and the number of cases receiving relief or wage assistance, 1933—1936, are given in appendix table 66.

³⁹The prevailing wage replaced the security wage on July 1, 1938 (Emergency Relief Administration Act of June 22, 1938, and WPA Administrative Order No. 41, June 22, 1938). In effect, the change amounted to retaining the monthly security payment but changing the hourly rate and the hours of work.

Cases Removed From the Relief Rolls in 13 Cities During 1935 by
Works Program Employment

Relief cases closed because of Works Program employment up to December 31, 1935, in the survey cities were equal to about 44 percent of the July 1935 relief load (appendix table 67). Approximately two-thirds of these closings occurred during December.⁴⁰

There was a sharp difference in representation of men and women on the Works Program. In terms of their respective relief populations, the proportion of women workers employed on the Program during 1935 was less than a fourth that of men. This was partly the result of difficulty encountered during the early months of the Program in providing suitable projects for women. Then, too, the head of the family, usually a man, was the one to be assigned to the Works Program.

Approximately equal proportions of the July 1935 relief load of Negro and white workers were employed on the Works Program. When, however, the proportions of the July load transferred to the Program are examined by sex, it is found that a much higher proportion of men than of women received assignment. Moreover, the proportion of Negro men was higher than the proportion of white men (appendix table 68). This was due to the large proportion of Negroes who were laborers, the largest occupational class on the Program.

The proportion of experienced workers on relief who obtained employment on the Works Program was over three times that of inexperienced workers. This resulted from the policy of assigning Works Program jobs to heads of cases who, as a rule, were experienced workers (appendix table 68).

Of the four major occupational groups—white-collar, skilled, semiskilled, and unskilled—assignments to the Works Program were relatively most numerous among the unskilled and least numerous among white-collar workers.

Comparison of Works Program Wage Rates With Relief Grants

Relief grants were based mainly upon need, and those for large families were necessarily much greater than those for small families (appendix table 69). But the monthly wage paid to a worker on the Works Program does not vary with the size of the case of which he is a member. Workers from relief cases which had received large grants were employed at unskilled labor on the Program in substantially the same proportion as workers whose

⁴⁰ A case leaving relief and accepting Works Program employment was not designated as a Works Program closing until receipt of the first full Works Program check. Inasmuch as payments were made twice a month in nearly all instances, Works Program closings for 1935 in the 13 cities do not include cases obtaining Works Program employment during the latter half of December 1935.

cases had received small relief grants, and the median wage rate was about the same for each type of case (appendix table 70).

Occupational skills are classified on the Works Program as unskilled, intermediate, skilled, and professional and technical. Four-fifths of all jobs on the Program in December 1935 called for unskilled workers.⁴¹ Wages of the bulk of the workers were, correspondingly, within narrow limits: the monthly wage rates⁴² of over three-fifths of the Program workers during the last quarter of 1935 were within the interval \$50—\$59.⁴³ Relief grants to these cases, though, during the last 30 days on relief, were within broad limits; the greatest concentration, which took in only a fourth of the cases, was of those receiving relief grants within the interval \$20—\$29 (appendix table 70).

The majority of the relief cases transferred to the Works Program benefited considerably from the transfer. The average relief grant to cases on relief throughout May 1935 ranged from \$10 for the one-person case to \$61 for cases of eight persons or more (appendix table 69). The Works Program wage rate exceeded the relief grant of the last 30 days on relief in 85 percent of the cases. In only 7 percent of the cases did the relief grant exceed the Works Program wage rate (appendix table 71). Works Program wage rates exceeded former relief grants by at least \$20 a month in about three-fourths of the cases studied and by at least \$40 a month in about one-third of the cases. Two-thirds of the family cases and 98 percent of the nonfamily cases had Works Program wage rates that exceeded their relief grants by \$20 a month or more.

There were, of course, cases in which relief grants exceeded Works Program wage rates. In 4 percent of all cases the situation was reversed and the relief grants were the larger by \$20 a month or more. Practically all of these were family cases

⁴¹ Eighty percent of the workers employed on the Works Program in the United States in December 1935 held unskilled jobs; corresponding proportions for June 1936 and May 1937 were 65 and 66 percent, respectively. See reports on progress of the Works Program published by the Works Progress Administration, Division of Statistics, Washington, D. C.

⁴² Data on actual monthly income from Works Program employment are not available from this study. Since the worker was paid for time lost because of bad weather and other like conditions which were beyond his control, the average monthly wage income was doubtless substantially the same as the average monthly wage rate.

⁴³ The present comparison of Works Program wage rates with former relief grants includes data for all relief cases closed because of Works Program employment in 13 cities during the last quarter of 1935 except those cases which had both Works Program and private employment (8 percent of total Works Program closings) and those in which the Works Program workers were over 64 years of age (2 percent of total). Inasmuch as all kinds of employment financed under the Emergency Relief Appropriation Act of 1935 (including both CCC and NYA employment) came within the scope of the study, a small number—approximately 1 percent—of the cases closed by Works Program employment had two members employed on the Program. In such cases, the Works Program wage rate used in the analysis is the sum of the two rates.

(appendix table 72). The wage rates fell below the former relief grants in nearly a tenth of the family cases. In some cities this deficiency was offset in part by supplementing the Works Program wage with relief; in other cities wage rates were increased by as much as 10 percent.⁴⁴

Private-Employment Income Compared With Former Relief Grants and With
Works Program Wage Rates

The distribution of relief grants and wage rates about their respective averages differed sharply. Relief grants fell within comparatively broad limits because of varying needs according to size of case. Works Program wage rates, because of the predominance of unskilled jobs on the Program, fell within very narrow limits. Private-employment wage rates, without these controlling factors, fell within very broad limits.

Private-employment income, at time of closing, averaged nearly three times as much as the amount of relief granted during the last 30 days on relief.⁴⁵ The difference was a little smaller for family cases but much larger for nonfamily cases (appendix table 74). The average difference held for both white and Negro cases, but among Negro cases the average relief and the average private income was about a third less, in each instance, than that for whites.⁴⁶

The average private-employment income was only a third greater than the average wage rate of cases transferred to the Works Program. There were wide differences, though, by race and size of case in variations from this average: the Works Program wage rate remained about the same for white, Negro, family, and nonfamily cases, but private-employment income was much higher for whites than for Negroes and for family cases than for nonfamily cases.

⁴⁴ Executive Order 7046 (May 20, 1935) authorized the Works Progress Administrator to adjust the "rate of earnings for any class of work in a locality by not more than 10 percent from the monthly earnings."

⁴⁵ Approximately 10 percent of the cases leaving the relief rolls with private employment had two or more members employed at the time of closing. The wage rate presented here for a given case is the sum of the wage rates of all its employed workers 16—64 years of age.

⁴⁶ Two facts may account for the difference between median relief grants to white and Negro cases. In the first place, Negro cases leaving the relief rolls were smaller than white cases. Negro cases leaving the relief rolls during 1935 averaged 2.2 persons a case as against 2.9 for whites. Negroes therefore required smaller relief grants. In the second place, average relief grants were smaller in the South than in the North. Inasmuch as Negroes constituted a larger proportion of total cases in the South than in the North, this lower relief grant in the South had greater effect upon the average for Negro cases than upon the average for white cases. Available evidence indicates that relief grants in the southern cities (Atlanta and Houston) included in this study were smaller for Negro cases of a given size than for white cases. In the remaining cities of the study there is no significant difference between relief grants to whites and Negroes by case size.

Half of the relief cases which had private employment at time of closing had wage rates of more than \$80 a month; in contrast, only about a half of the relief cases with private employment had received more than \$30 a month during the 30 days preceding the last relief grant. Nine-tenths of the relief cases had grants of less than \$60 a month, while three-fourths of the cases on the Works Program had wage rates of less than this amount. But only a fifth of the private-employment wages were less than \$60 (appendix tables 70 and 73).

Income from private employment was greater than the amount of relief formerly received in over 90 percent of all cases leaving the relief rolls with such employment. This condition prevailed for family and nonfamily cases and also for white cases. The corresponding proportion for Negro cases was about 85 percent.

Private-employment income exceeded former relief grants by \$40 a month or more in nearly three-fourths of the cases, by \$60 or more in almost one-half, and by at least \$80 in nearly one-third of the cases. These differences were substantially the same for family, nonfamily, and white cases but were smaller for Negro cases (appendix table 75).

Relief grants exceeded private-employment income in a small proportion of the cases where such income was obviously insufficient to close the case; most of these were closed because of aid from relatives and friends and because of resources discovered by the agency.

Utilization of the Skills of Workers on the Works Program

Works Program jobs were concentrated largely in the unskilled category. This resulted from difficulties encountered in providing semiskilled, skilled, and white-collar work which would not compete with private industry and which would require only minimum outlays for equipment, materials, and nonrelief supervision. Unskilled jobs comprised more than four-fifths of all those on the Works Program held by experienced workers in relief cases in the 13 cities closed by December 31, 1935. In terms of their usual occupations, however, less than a half of these workers were in the unskilled group. This meant that white-collar, skilled, and semiskilled workers assigned to the Program had accepted jobs outside their usual occupations.

In view of occupational differences between whites and Negroes on relief, the proportion of employed Negroes on the Works Program holding unskilled jobs exceeded that of whites. Because of the placement of women in semiskilled work on Works Program sewing projects and because of the larger proportion of women among Negro workers than among white workers, the proportion of employed Negroes doing semiskilled work was greater than that of whites (appendix table 76).

Occupational Shifts

Comparatively few workers other than those in the unskilled group were assigned to Works Program jobs in their usual occupations. About nine-tenths of all unskilled workers assigned to the Program were given unskilled jobs; less than a third of all assigned white-collar workers were given white-collar work; and the proportions of all assigned skilled and semiskilled workers given jobs at their usual occupations were even smaller—a seventh and a tenth, respectively. Only a small percent of the experienced workers transferred from relief rolls in the 13 cities to the Works Program during 1935 held jobs in occupational levels higher than those in which they usually worked; the great bulk was rather evenly divided between those who held jobs in their usual occupational groups and those who had accepted jobs in an occupational level lower than that in which they usually worked. It should be noted, however, that white-collar workers, by definition, could not move upward in the occupational scale and that unskilled persons could not move downward. Of those who could move upward, only a small percent actually did so, but over three-fourths of those who could move downward accepted jobs in occupational levels lower than those of their usual employment. Nearly all of the downward movement was into unskilled work, since most of the Works Program jobs were in that category (appendix tables 76 and 77).

A somewhat greater proportion of Negroes than whites on the Works Program were assigned jobs at their usual occupations. This difference was due to two factors. First, more Negroes than whites on relief were unskilled workers, and transfers from relief to the Program approximated a cross section of the relief load. Second, most of the jobs on the Program, for either whites or Negroes, were unskilled. The transfer of the employable relief load to the Works Program, therefore, necessarily resulted in a greater occupational shift downward of white workers than of Negroes. Accordingly, about a half of all white workers transferred to the Program shifted downward, while slightly over a fourth of the Negro workers did so. Nearly all of this shift, for both racial groups, was into unskilled work.

Table 20.—Average Monthly Accession and Separation Rates of Relief Persons, by Age and Sex, Age and Race, and Sex and Race, 13 Cities, January—December 1935

Description	Accession rate (percent)			Separation rate (percent)		
Age by sex						
	Total	Male	Female	Total	Male	Female
All ages.....	4.3	4.6	4.1	5.3	5.5	5.1
Under 16 years.....	3.9	3.9	3.9	5.0	5.0	5.0
16—24 years.....	4.8	4.8	4.7	5.9	6.0	5.8
25—44 years.....	4.9	5.6	4.3	6.1	6.9	5.5
45—64 years.....	4.1	4.4	3.6	4.5	4.8	4.2
65 years and over.....	3.8	4.0	3.5	3.8	3.8	3.7
Age by race						
	Total ¹	White	Negro	Total	White	Negro
All ages.....	4.3	4.9	2.7	5.3	6.0	3.4
Under 16 years.....	3.9	4.6	2.2	5.0	5.8	3.0
16—24 years.....	4.8	5.4	2.9	5.9	6.6	3.6
25—44 years.....	4.9	5.6	3.2	6.1	7.0	4.0
45—64 years.....	4.1	4.5	2.6	4.5	5.0	2.9
65 years and over.....	3.8	4.1	2.5	3.8	4.0	3.1
Sex by race						
	Total ¹	White	Negro	Total	White	Negro
Both sexes.....	4.3	4.9	2.7	5.3	6.0	3.4
Male.....	4.6	5.1	2.9	5.5	6.2	3.5
Female.....	4.1	4.7	2.5	5.1	5.8	3.3

¹Includes "other" races amounting to about 2 percent of the total number of persons on relief.

Table 21.—Average Monthly Accession and Separation Rates of Relief Cases, by Size of Case, 13 Cities, January—December 1935

Size of case	Accession rate (percent)	Separation rate (percent)
All sizes	5.0	5.6
1 person	7.5	6.8
2 persons	4.7	4.6
3 persons	4.6	5.7
4 persons	4.3	5.8
5 persons	3.9	5.3
6 persons	4.1	5.3
7 persons	3.7	5.2
8 persons or more	3.5	4.9

Table 22.—Average Monthly Accession and Separation Rates of All Workers on Relief, by Sex and Race, 13 Cities, 1935

Sex	Accession rate (percent)			Separation rate (percent)		
	Total ¹	White	Negro	Total ¹	White	Negro
Both sexes	4.9	5.4	3.3	5.6	6.2	3.9
Male	5.1	5.6	3.5	6.0	6.6	3.9
Female	4.2	5.0	2.9	4.8	5.3	3.9

¹Includes "other" races amounting to less than 2 percent of all workers on relief.

Table 23.—Average Monthly Accession and Separation Rates of Experienced Workers on Relief, by Usual Occupational Group, 13 Cities, 1935

Usual occupational group	Accession rate (percent)	Separation rate (percent)
Total	5.1	5.9
White-collar	4.9	5.0
Professional and technical	5.1	5.6
Managerial	5.7	5.1
Clerical	4.6	4.9
Skilled	5.1	6.6
Semiskilled	5.5	6.5
Unskilled	4.8	5.5
Manual	5.6	6.3
Domestic and personal service	4.1	4.7

¹Excludes cases which, because of strike or temporary layoff, had no private employment income.²All races are included in this total. Whites and Negroes constitute more than 98 percent of all cases admitted to relief in 13 cities during the year.³The comparable proportion of supplemented cases in the total relief load for May 1935 in these cities was 13.4 percent, according to a sample survey taken.

¹Carmichael, F. L. and Payne, Stanley L., *The 1935 Relief Population in 13 Cities: A Cross-Section*, Research Bulletin Series I, No. 23, Division of Social Research, Works Progress Administration, December 31, 1935, p. 14. This study of the May 1935 relief population was based upon a sample ranging from 1 percent of the total load in Chicago to approximately 10 percent in the smaller cities. The aggregate (44,174 cases) constituted 4 percent of the May 1935 relief load. Each city was assigned a weight based upon the relation of its relief load to the relief load of the 13 cities. The weights so determined for the 13 cities were then adjusted, by application of a constant factor, to yield a weighted aggregate of 10,000 cases. Of this number 1,066 cases were on relief only a part of May and 359 cases did not report supplementation status. The remainder (8,576 cases), on relief throughout May, were distributed by case size as shown here.²Occupational Characteristics Survey conducted as of May 1934 by the Division of Social Research, Works Progress Administration. With 1 exception (Omaha) the 13 cities on which the present report is based were included in the 79 cities surveyed. Data for these 12 cities are shown in the 12-city column. Data on the 79 cities surveyed are published in the study by Palmer, Gladys L. and Wood, Katherine D., *Urban Workers on Relief*, Part I—The Occupational Characteristics of Workers on Relief in Urban Areas May 1934, Research Monograph IV, Division of Social Research, Works Progress Administration, Washington, D. C., 1936, p. 61.

Note: The May 1934 and the May 1935 tabulations differ in 2 important respects. First, the May 1934 tabulation includes all cases on the relief rolls at some time during the month, while the May 1935 tabulation is limited to cases which were on relief throughout the month. Second, in the May 1934 tabulation cases with members on strike were regarded as having private employment, whereas in the May 1935 tabulation such cases (without earnings from any source) were not regarded as having private employment.

62 • CHANGING ASPECTS OF URBAN RELIEF

Table 41.—Average¹ Monthly Relief Benefit to Supplemented and Nonsupplemented Cases on Relief Throughout May 1935, by Size of Case, 13 Cities

Size of case	Nonsupplemented cases	Supplemented cases	Ratio of supplemented case benefit to nonsupplemented case benefit (percent)
Total cases reporting-----	7,408	1,142	
All sizes-----	\$28	¹ \$22	79
1 person-----	13	10	77
2 persons-----	22	18	82
3 persons-----	29	22	76
4 persons-----	33	27	82
5 persons-----	40	30	75
6 persons-----	44	36	82
7 persons-----	51	41	80
8 persons-----	56	43	77
9 persons-----	60	44	73
10 persons or more-----	73	57	78

¹ This is a "standardized" average. It was derived by weighting the average relief grants of supplemented cases of a given size by the number of nonsupplemented cases of the same size. Such weighting, made necessary by the overrepresentation of large cases in the supplemented group, yields an average which is directly comparable with the average for the nonsupplemented group. The unweighted average of the supplemented cases is \$27.

Table 42.—Average¹ Monthly Income of Supplemented and Nonsupplemented Cases on Relief Throughout May 1935, by Size of Case, 13 Cities

Size of case	Relief of nonsupplemented cases	Income of supplemented cases			Ratio of income of supplemented cases to relief of nonsupplemented cases (percent)

10 persons or more-----	73	99	57	42	136	78	58

¹ Arithmetic mean.

² Relief grants and nonrelief earnings only; income from other sources is disregarded.

Note: Relief-grant and private-employment income averages for supplemented cases, presented in this table for all case sizes combined, are standardized averages. They were derived by weighting the average for a given case size by the number of nonsupplemented cases of the same size. The unweighted averages for supplemented cases are: relief grants, \$27; private-employment income, \$24; relief-grant and private-employment income, \$51. The weighted averages—\$22, \$20, and \$42, respectively—are directly comparable with the average relief grant of nonsupplemented cases (\$28).

Table 43.—Portion of Nonrelief Earnings Accruing to Supplemented Cases as Income in Excess of the Relief Grant to Nonsupplemented Cases on Relief Throughout May 1935, 13 Cities¹

Size of case	Average monthly income			Average monthly nonrelief earnings of supplemented cases

High (January)	9,882,000	High (February)	4,950,000
Low (October)	6,568,000	Low (November)	3,627,000
Average	7,948,000	Average	4,116,000

¹Revised series of unemployment estimates made by Robert R. Nathan. See *Selected Current Statistics*, Social Security Board, Vol. 2, No. 3, Washington, D. C., September 1937, p. 58. The relief and wage assistance series is an extension and revision of the one appearing in the Division of Research, Statistics, and Records, *Monthly Report of the Federal Emergency Relief Administration, June 1 Through June 30, 1936*. Federal Emergency Relief Administration, Washington, D. C., 1937, p. 2.

Table 67.—Proportion of Relief Cases Closed During 1935 Because of Works Program Employment, by Race, Employability, and Size of Case, 13 Cities

Race, employability, and size of case	Cases on relief July 1935	Cases closed by Works Program employment	
		Number	Percent of July 1935 load
Total	345,500	151,821	43.9
RACE			
White	251,200	110,173	43.9
Negro	89,500	39,313	44.4
Other	5,800	2,335	40.3
EMPLOYABILITY ¹			
Cases with workers	307,700	148,524	48.3
Cases without workers	37,800	3,297	8.7
SIZE OF CASE			
1 person	77,400	31,372	40.5
2 persons	73,900	34,899	47.2
3 persons	59,800	26,429	44.2
4 persons	49,400	22,283	45.1
5 persons	35,400	14,987	42.3
6 persons	20,400	9,194	45.1
7 persons	12,500	5,790	46.3
8 persons	7,400	3,012	40.7
9 persons	4,500	1,913	42.5
10 persons or more	4,800	1,942	40.5

¹In this study a worker has been defined as any person 16 to 64 years of age, inclusive, who is either working or seeking work. Since there is no definite upper age limit on the Works Program, it was possible for some relief cases that were technically without "workers" to be transferred to the Program.

Table 68.—Workers Transferred From Relief to the Works Program, by Race, Sex, and Experience Status, 13 Cities, July—December 1935

Race, sex, and experience status	Workers on relief July 1935	Workers in cases transferred to Works Program as percent of July load		
		Total	Employed on Works Program	Not employed on Works Program
Total ¹	447,300	46.0	33.3	12.7
RACE AND SEX

¹The sample of the May 1935 case load taken varied from 1 percent in Chicago and 4 percent in Detroit and St. Louis to approximately 10 percent in the smaller cities. The sample yielded 14,174 cases or about 4 percent of the May 1935 case load. In computing the aggregate for 13 cities, each city was weighted according to its May 1935 case load and the aggregate reduced arbitrarily to 10,000 cases. Of this total 7,428 cases were reported on relief throughout May 1935 and without private-employment income. For further details see Carmichael, F. L. and Payne, Stanley L., *The 1935 Relief Population in 13 Cities: A Cross-Section*, Research Bulletin Series I, No. 23, Division of Social Research, Works Progress Administration, Washington, D. C., December 31, 1936.

²Median.

¹4 occupational groups are considered—white-collar, skilled, semiskilled, and unskilled. If a person's employment on the Works Program is in an occupational group other than his usual one, it is said that there was an "occupational shift." A shift toward the white-collar level has been termed an "upward shift," while a shift toward the unskilled level has been termed a "downward shift." By definition white-collar workers cannot shift upward and unskilled workers cannot shift downward.

²Includes "other" races.

Appendix B

LIST OF TABLES

<i>Table</i>	<i>Page</i>
1. Proportion of persons in the general population receiving first relief in 1935, by age, sex, and race, 13 cities -	43

11. Trend of the relief and wage assistance load, by size of case, 13 cities, December 1934—December 1935 - - - - -	46
12. Trend of relief or wage assistance to cases with workers and cases without workers, 13 cities, December 1934—December 1935 - - - - -	47
13. Workers receiving relief or wage assistance, by race, sex, and experience status, 13 cities, December 1934 and December 1935 - - - - -	47
14. Experienced workers receiving relief or wage assistance, by usual occupational group, 13 cities, December 1934 and December 1935 - - - - -	47

Table

Page

15. Trend in occupational distribution of experienced workers receiving relief or wage assistance, 13 cities, December 1934—December 1935 - - - - -	48
16. Experienced workers receiving relief or wage assistance, by usual industrial group, 13 cities, December 1934 and December 1935 - - - - -	48
17. Trend of employment in the United States and of experienced workers receiving relief or wage assistance, by usual industrial group, 13 cities, December 1934—December 1935 - -	49
18. Cases admitted to the relief rolls, by type of accession, 13 cities, 1935 - - - - -	49
19. Monthly accession and separation rates of cases, persons, and workers receiving relief or wage assistance, 13 cities, 1935 - - - - -	50
20. Average monthly accession and separation rates of relief persons, by age and sex, age and race, and sex and race, 13 cities, January—December 1935 - - - - -	50
21. Average monthly accession and separation rates of relief cases, by size of case, 13 cities, January—December 1935-	51
22. Average monthly accession and separation rates of all workers on relief, by sex and race, 13 cities, 1935 - - - - -	51
23. Average monthly accession and separation rates of experienced workers on relief, by usual occupational group, 13 cities, 1935 - - - - -	51
24. Monthly accession rates of experienced workers on relief, by usual industrial group, 13 cities, 1935 - - - - -	52
25. Monthly separation rates of experienced workers on relief, by usual industrial group, 13 cities, 1935 - - - - -	52
26. Reason for opening relief cases, 13 cities, 1935 - - - - -	53
27. Reason for opening new relief cases, 13 cities, 1935 - - -	54
28. Reason for reopening relief cases, 13 cities, 1935 - - - -	55
29. Reason for closing relief cases, 13 cities, 1935 - - - - -	56
30. Reason for opening family and nonfamily relief cases, 13 cities, March—December 1935 - - - - -	57
31. Reason for closing family and nonfamily relief cases, Works Program closings excluded, 13 cities, March—December 1935-	57
32. Reason for closing relief cases without workers 16 through 64 years of age, by race, 13 cities, May and October 1935-	58
33. Experienced and inexperienced workers in regular closings, by race and employment status, 13 cities, July—December 1935 - - - - -	58
34. Usual occupational group of workers on relief and usual and current occupational group of workers having private employment at closing, by race, 13 cities, July—December 1935-	58
35. Usual occupational group of employed workers, by occupational group of private employment at time of regular closing and by race, 13 cities, July—December 1935 - - - - -	59
36. Usual industrial group of workers on relief and usual and current industrial group of workers having private employment at time of regular closing, by race, 13 cities, June—September 1935 - - - - -	59
37. Shift from usual industrial group by workers having private employment at time of regular closing, 13 cities, June—September 1935 - - - - -	60

<i>Table</i>	<i>Page</i>
38. Usual industrial group of employed workers, by industrial group of employment at time of regular closing and by race, 13 cities, June—September 1935 - - - - -	60
39. Proportion of cases admitted to the relief rolls having 1 person or more employed at time of opening, by race, 13 cities, 1935 - - - - -	61
40. Proportion of cases on relief also having private employment, by size of case, in 13 cities, May 1935, and in 12 cities and 79 cities, May 1934 - - - - -	61
41. Average monthly relief benefit to supplemented and nonsupplemented cases on relief throughout May 1935, by size of case, 13 cities - - - - -	62
42. Average monthly income of supplemented and nonsupplemented cases on relief throughout May 1935, by size of case, 13 cities - - - - -	62
43. Portion of nonrelief earnings accruing to supplemented cases as income in excess of the relief grant to nonsupplemented cases on relief throughout May 1935, 13 cities - - - - -	63
44. Proportion of experienced workers in relief accessions who were employed at time of opening, by race and sex, 13 cities, 1935 - - - - -	63
45. Occupational group of jobs held by workers employed while on relief, by race, in 12 cities and 79 cities, May 1934, and relief accessions in 13 cities, 1935 - - - - -	64
46. Industrial group of jobs held by workers employed while on relief, by race, in 12 cities and 79 cities, May 1934, and relief accessions in 13 cities, 1935 - - - - -	64
47. Duration of unemployment of experienced workers in relief accessions and separations, by race, 13 cities, 1935 - - - - -	65
48. Average duration of unemployment of workers admitted to relief, by race, age, and sex, 13 cities, February—May 1935 - - - - -	65
49. Average duration of unemployment of workers admitted to relief, by race and usual occupational group, 13 cities, January—December 1935 - - - - -	66
50. Duration of unemployment of workers securing jobs at closing, regular and Works Program closings, 13 cities, October—December 1935 - - - - -	66
51. Average duration of unemployment of experienced workers in regular and Works Program closings, by race, sex, and age, 13 cities, October—December 1935 - - - - -	67
52. Average duration of unemployment of all workers and for workers securing jobs, regular and Works Program closings, by age, race, and sex, 13 cities, October—December 1935 - - - - -	68
53. Average duration of unemployment of employed workers in regular and Works Program closings, by race, sex, and age, 13 cities, October—December 1935 - - - - -	69
54. Duration of unemployment for experienced workers securing employment at closing, regular and Works Program closings, by sex and race, 13 cities, October—December 1935 - - - - -	70
55. Average monthly separation rates of workers on relief, regular closings, by age, experience status, and employment status, 13 cities, October—December 1935 - - - - -	71

Table

Page

56. Average monthly separation rates of workers on relief, regular closings, by race, sex, experience status, and employment status, 13 cities, October—December 1935 - - - - -	72
57. Average monthly separation rates of workers on relief, regular closings, by usual occupational group, 13 cities, October—December 1935 - - - - -	74
58. Average monthly relief load of inexperienced workers, by sex and age, 13 cities, October—December 1935 - - - - -	75
59. Average monthly separation rates of experienced workers on relief, by duration of unemployment, 13 cities, October—December 1935 - - - - -	75
60. Average monthly separation rates of experienced workers on relief, by duration of unemployment, age, sex, and race, 13 cities, October—December 1935 - - - - -	76
61. Average monthly reemployment rates of experienced workers on relief, by duration of unemployment and age, 13 cities, October—December 1935 - - - - -	77
62. Duration of unemployment of experienced workers on relief, by age, sex, race, and usual occupational group, 13 cities, September—November 1935 - - - - -	78
63. Average monthly reemployment rates of experienced workers on relief, by duration of unemployment, race, and sex, 13 cities, October—December 1935 - - - - -	79
64. Average monthly reemployment rates of experienced workers on relief, by usual occupational group, 13 cities, October—December 1935 - - - - -	79
65. Average monthly reemployment rates of experienced workers on relief, by duration of unemployment and usual occupational group, 13 cities, October—December 1935 - - - - -	80
66. Number of persons unemployed and number of cases receiving relief or wage assistance, 1933—1936 - - - - -	80
67. Proportion of relief cases closed during 1935 because of Works Program employment, by race, employability, and size of case, 13 cities - - - - -	81
68. Workers transferred from relief to the Works Program, by race, sex, and experience status, 13 cities, July—December 1935 - - - - -	81
69. Relief income of cases on relief throughout May 1935 with no private-employment income, 13 cities - - - - -	82
70. Distribution of monthly Works Program wage rates of closed relief cases, by amount of relief granted same cases during last 30 days on relief, 13 cities, October—December 1935 - - - - -	83
71. Comparison of monthly Works Program wage rates with relief grants to the same cases during last 30 days on relief, Works Program closings, by race and family status, 13 cities, October—December 1935 - - - - -	84
72. Differentials between monthly Works Program wage rates and relief grants to same cases during last 30 days on relief, Works Program closings, 13 cities, October—December 1935 - - - - -	84
73. Monthly private-employment wage rates of closed relief cases, by amount of relief granted same cases during last 30 days on relief, 13 cities, October—December 1935 - - - - -	85

<i>Table</i>	<i>Page</i>
74. Average Works Program and private-employment wage rates compared with average relief grants to same cases during last 30 days on relief, by race and family status, 13 cities, relief cases closed October—December 1935 - - - -	86
75. Differentials between monthly private-employment wage rates and relief grants to same cases during last 30 days on relief, by family status and race, 13 cities, relief cases closed October—December 1935 - - - - -	86
76. Usual occupational group of employed workers, by occupational group of Works Program employment at time of relief closing and race, 13 cities, July—December 1935 - - - - -	87
77. Shift from usual occupational group by employed experienced workers in Works Program closings, by race, 13 cities, July—December 1935 - - - - -	88
